Project Team Member:

Hello! We're members of the LuminaEye project team. Thank you so much for taking the time to speak with us. What's your main way of commuting to and from work these days? Have you encountered any situations that were particularly inconvenient for you?

(System prompt: You can only send 1 text message every 24 hours until the other person follows you or replies.)

Interviewee:

I still have some residual vision, so I use a phone map and a white cane to get around. The problem is, the phone only gives general directions, like getting me to a certain intersection. But on the stretch from the intersection to my office door, shared bikes are often left randomly, and delivery e-scooters are parked on the tactile paving. I have to navigate around them very carefully, and sometimes after I've gone around, I don't know where I am anymore.

Project Team Member:

So the navigation and obstacle avoidance during those "last few dozen meters" is something that bothers you?

Interviewee:

Exactly. If there were a pair of glasses that could tell me, "Shared bike ahead, two meters away. Please go around on the left," and also let me know if I've strayed from the tactile paving, that would make me feel so much safer. Sometimes I'll go around an obstacle, and then I can't find the tactile paving again, so I have to stop and ask for help.

Project Team Member:

Hello! We're from the Lumina Eye assistive glasses project team. Thank you so much for helping us with our research. What do you find the most difficult situation to handle when you're out walking?

Interviewee:

Crossing the street. Some intersections have audio signals, but many don't. I just stand by the curb and listen to the traffic, and when it sounds like the cars have stopped, I go. But sometimes cars are turning, or some e-scooters run red lights. I'll be halfway across when I suddenly hear a car coming close, and it panics me. Also, some intersections have really short green lights. I walk slowly, and I'm scared I won't make it to the other side in time.

Project Team Member:

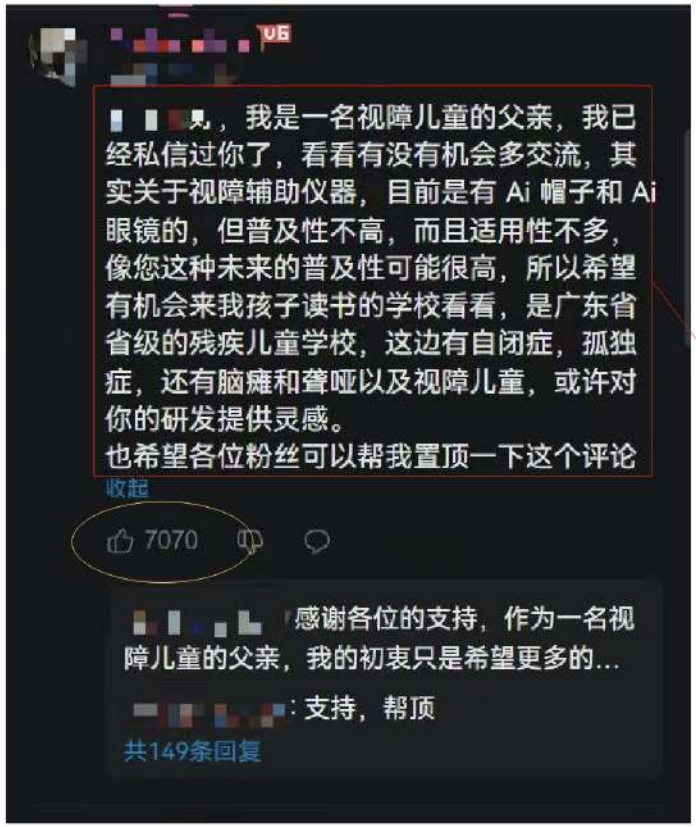
If there were a pair of glasses that could tell you the current traffic light status and how much time is left, do you think that would help?

Interviewee:

It would definitely help. At least I'd know if it's red or green, instead of having to guess.

Interviewee:

It would be even better if it could say, "Green light has 6 seconds remaining. Recommend waiting for the next green." Then I could decide for myself whether to cross or not. Right now, I rely entirely on listening, and if I get it wrong, it's really dangerous.



I am the father of a visually impaired child. Currently, there are Ai hats and Ai glasses available as assistive devices for the visually impaired, but their popularity is not high and their applicability is limited. For someone like you, the future popularity might be quite high. Therefore, I hope to have the opportunity to visit the school where my child studies. It is a provincial-level special education school in Guangdong Province. Here, there are children with autism, Asperger's syndrome, cerebral palsy, deafness, and visual impairments. Perhaps this can provide inspiration for your research
